DAIMLER

FuelCell Energy

**MOTOROLA** 

INTELLIGENT ENERGY

Standards and Technology Technology Administration U.S. Department of Commerce

#### **Overview**

- Growing populations, rising standards of living, and increased urbanization leads to a escalating volume of waste.
- Huge volumes of waste are collected in dumps, creating a major environmental issue.
- Wastewater treatment plants generate noxious gasses that are released in the environment.
- Technological developments, economic conditions, and public policy trends are now aligning to create a significant market opportunity for waste-toenergy (WTE) plants, which utilize municipal solid waste (MSW) and wastewater from treatment plants for the production of electricity and heat.

#### Waste H2 sources include:

- Waste bio-mass: biogas to high temp fuel cells to produce H2 there are over two
  dozen sites where fuel cells have been installed- over 9 MW
- **Chlor-alkali plants**: Hydrogen is created as a by-product manufacturing of chemicals like chlorine. This can be captured and transported for use or used to help power the plants themselves (GM and Dow Chemical had a Demo Program)
- Reduction furnace operations: metal powder, heat treatment, -- FCE is pursuing this market—Demo project under DOE-ITP program in NJ
- Hydrocarbon waste: can produce hydrogen using high temp fuel cells-such as DFC or SOFC—Paint fume from Ford Motors plant in Canada- FCE's fuel cell
- Total market is above 100,000 MW world-wide for all these.
- NOTE: Each of these opportunities have different clean up requirements.

#### Why Renewable Hydrogen?

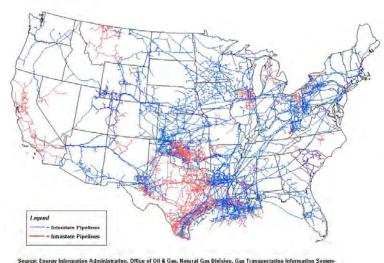

- More effective use of waste hydrogen, adds to overall supply, greens the source of energy, and ultimately should help lower the cost of hydrogen.
- Turns a wasted asset into either a marketable product or increased operational efficiency within a plant.
- Using hydrogen helps mitigate the intermittency of renewable energy sources by providing opportunities for storage.
- In the US, there are:
  - 150 manufacturing facilities where hydrogen is currently not recovered
  - 40,000 waste treatment facilities that could be modified to generate hydrogen

#### **Fuel Flexibility**

Biogas: generated from organic waste

- Wastewater treatment plants can provide multiple MW of renewable power
- Agricultural and food processing plants can turn waste into power

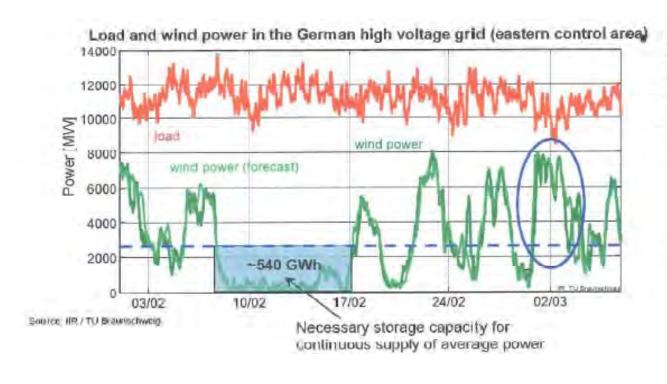

#### **Integrate Intermittent Energy Sources**

Renewable sources are variable. Surplus generation is often wasted and power plants must be fired up to deal with valleys in supply.

Significant power fluctuations from the mean and from forecasts

- Short term (minutes)
- Long term (days)
- Seasonal (months)

#### **Advantages of Biomass Hydrogen for Energy Storage**

- •Maximizes Value of Solar and Wind and other renewables
- Distributed Generation
- No fuel consumption in frequency regulation (standby) state
- •Rapid Load following capability (quickly increase power to meet demand)
- •High (more than 50-percent) efficiency regardless of output level
  - Superior to micro-turbines or diesel gensets
- Zero emissions
- Super-peaking capability can exceed 100 Percent of rated capacity

# Hydrogen can be made renewable in significant quantities and is sustainable

- US: 40,000 anaerobic digester facilities: 10.8 TCF of H2 (
   128 Million cars)
- •US: Landfill gas facilities: 7 TCF (82 Million cars)
- Biogas fuels approximately 210 Million cars

#### Chlor-alkalai

- Estimated 389 thousand metric tons of hydrogen annually produced from chlor-alkali processes alone are equivalent to the annual fuel consumption of 1.8 million light-duty hydrogen vehicles.
- World production of chlor-alkali hydrogen = 1,438 thousand metric tons/year
- 216 thousand metric tons/year -- 15% of the chlor-alkali hydrogen production -- is vented by chlor-alkali industry
- Potential electricity if vented H2 were used in fuel cells: 420
   MWe (assuming 50 % conversion efficiency)
- Approximately 70 percent of the United States chlor-alkali production capacity is in the Gulf Coast region.
  - Could support the numerous DOD facilities in the region

#### **Biogas**

- Biogas, including anaerobic digester gas, can be reformed to produce hydrogen and used in a fuel cell to produce significant amounts of electricity and heat.
- When biogas is produced and used on-site in a fuel cell, fuel utilization or overall energy efficiency can reach 90% and can reduce emissions by more than 90% by weight as compared to the emissions associated with grid electricity generation.
- In addition to fuel cells for on-site power generation, the hydrogen produced using biogas can be used to power vehicles.
- Wastewater treatment plants (WWTPs), waste streams from food and beverage processing plants, crop farms and animal feed facilities, and municipal landfills are all biogas sources.

#### **California Biogas Potential**

#### **Wastewater Treatment**

- Wastewater treatment plants release methane, which is normally burned off into CO<sub>2</sub> and released into the air.
- Methane from plants can provide power using fuel cells. Already producing 8+ MW in CA.
- Free, renewable energy: 250 kW 3 MW per plant.
  - Enough to power up to 3,000 homes.
- Hydrogen from reformed waste methane can also power fuel cell cars.
   Already happening at Orange County Sanitation in Fountain Valley.

#### California Biogas Potential

#### **Untapped Potential**

- CA has capacity to derive 100 MW of power from wastewater treatment plant emissions.
- Other organic waste sources can also be used.
- Biodegradable waste from dairies, food processing plants, livestock and poultry farms, and restaurant oil and grease increase this potential to 450+ MW.
  - That's enough to power 400,000+ homes.
- This power is available 24/7 using fuel cells and could be used to buffer other renewables.

# Biogas / Waste Project in San Diego (with FCE and UCSD)

- Purification system, developed by Biofuels Energy, to process gas generated by landfills, sewage treatment plants, and large livestock facilities into usable methane.
- Fuel Cell Energy's molten carbonate fuel cells installed at two San Diego treatment plants and on the UC San Diego campus
- 4.5 megawatts generating capacity to generate heat and electricity

#### Fountain Valley, CA Station

- Anaerobic digestion of municipal wastewater
- Converts sludge to electricity, hydrogen and heat
- 100 kg/day capacity (25 cars) and 250Kw of Power
- Host site: Orange County Sanitation District
  - Water waste from 100,000 people provide 1MW of power and 500 kg/day of Hydrogen
  - ~40,000 waste water digesters in the U.S.

#### **South Carolina**

- Landfill gas to generate hydrogen for fuel cell powered materials handlinge quipment
- Involves BMW, DOE, Natural Gas Institute, SC Energy office, and SC Hydrogen and Fuel Cell Alliance
- Landfills generate landfill gas (LFG) from active microorganisms interacting with the waste.
- This gas can be converted into hydrogen and used to provide energy or fuel, effectively turning trash into power.
- DOE Goals: To show that LFG, cleaned up and reformed, can be used to power material handling equipment (MHE)

#### What is needed

- Integration of fuel cells and hydrogen with DOE and DOD biomass, biofuels and biogas programs to develop the technologies for this market
- Funding for gas purifiers
- Expand demonstration projects to include Chlor-alkali, biorefining and hydrogen delivery/distribution infrastructure.

#### Summary

- ✓ Distributed generation: power at the point of use reduces need for congested, faulty, and inefficient transmission and distribution lines
- ✓ Resource maximization: get the most out of fuels and take advantage of existing gas infrastructure and waste gas stream
- ✓ Renewable integration: excess renewable power can be stored as hydrogen and used for power on demand or to fuel vehicles
- ✓ Environment: fuel cells increase efficiency and reduce emissions of all kinds
- ✓ Economy: save money, create jobs and support economic growth here in the USA
